

Checking an order’s supplier folder

Type a PO number and the app reads the supplier’s folder for that order, tells you what looks wrong, and shows you everything it looked at. Two checks: cover pages that don’t belong, and files whose name has drifted. The same check can also be run across every order at once — section 6.

Checks in the sidebar, just under **Delivery**. Open to reviewers and admins alike. **Check every PO**, top right, is the fleet-wide version.

1 What this page asks that Delivery doesn’t

The two pages read the same folder from opposite ends, and that is why they are two pages.

Delivery	Checks
- Starts from what we owe the supplier. - Asks: <i>did everything arrive?</i> - A stray file is, at most, one anonymous number.	- Starts from what is actually in the folder. - Asks: <i>is anything in here that shouldn’t be, or under the wrong name?</i> - Names the file, says which style it answers to, and offers a remedy.

The folder belongs to the order, not to one style

A purchase order gets **one** folder, shared by every style on it — and most POs carry several styles. So both checks resolve the **whole order** before they judge a single file. Judging a file against one style’s expectations would propose removing its neighbour’s artwork.

2 Running a check

One field. Type the PO number, press **Run checks**, and wait a moment while the folder is read — it is several round-trips to SharePoint, so it isn’t instant.

- 1 Run checks** reads the folder now. The address bar keeps the PO number, so a finding can be pasted to a colleague and they land on the same order.
- 2 Re-scan everything** throws the picture away and reads the folder again. Do this if you have been sitting on the page a while — a scan is a snapshot, and colleagues rename things.

- 3 The header names what was checked — the supplier, how many styles are on the order, the exact folder path, and every style number. **Open the folder** takes you to it in SharePoint.

If the PO appears under two suppliers

Two orders can share a reference, and each supplier has their own folder. The page will not guess: it lists the suppliers and asks you to pick one.

3 Two groups: what looks wrong, and what was looked at

Each check reports the same two things. The flagged rows come first, with the app’s suggested remedy already ticked. Underneath, a line you can open that lists **every file that was scanned and is fine** — because “0 problems” and “nothing was looked at” are otherwise indistinguishable.

Cover pages in the PO folder

Every style on this purchase order shares one folder, so the covers that belong in it are the covers of all of them.

5 files scanned · 2 flagged 1

☒ 00-4471-navy-cover-page.pdf 4471

An old copy of 4471’s cover — the current one is already in the folder.
4471 now delivers its cover as “00-4471-dark-navy-cover-page.pdf”, which is present. Nothing reads this file any more.

Open

☐ Cover Page (2).pdf PO folder 4

Cover-page-shaped, but not named by this app.
It does not follow the naming convention, so it was not generated here — it may well be the supplier’s or the customer’s own file. This file is in the PO folder itself, not in APPROVED LAYOUTS.

Report only — no action offered. 5

Re-check

Show the 3 files that look right 6

- 1 “5 files scanned · 2 flagged” is the coverage line. The first number is how many files this check actually judged; the second is how many it has something to say about.
- 2 A ticked action is a suggestion, not a decision. Where the app can explain a finding in one sentence it pre-selects the remedy. Where it can’t, the row arrives with **nothing ticked** — that reads as “go and look at this”, not “we are about to remove it”.
- 3 Re-check re-reads the folder for that one row and tells you whether it is still a finding, without reloading the page or losing your other ticks. **Apply to this file** does just that row.
- 4 The “PO folder” tag means the file sits in the order’s own folder rather than in **APPROVED LAYOUTS**. Those files are reported so you can see them, and never offered a button — see section 5.
- 5 “Report only” means the check has nothing safe to offer. Deal with it in SharePoint yourself if it needs dealing with.
- 6 Open the second group to see every file that passed and the one-line reason it passed. This is what makes a clean result believable.

4 The two checks, and what their verdicts mean

Cover pages in the PO folder. Anything cover-page-shaped, matched against the covers the whole order expects — both the name each style delivers under *today* and the name it was generated with.

THE VERDICT SAYS	WHAT IT MEANS, AND WHAT IS OFFERED
The cover this PO expects for 4471.	Fine. It sits in the second group.
An old copy of 4471’s cover — the current one is already in the folder.	The naming rule moved on and the correct file is already there. Delete is suggested; renaming would collide.

4471's cover, under the name it was generated with.	The only copy, under an out-of-date name. Rename in place is suggested — the file is correct, only its name is behind.
A cover for "5099" — no style on this PO has that number.	It follows this app's convention, so it was generated here and landed in the wrong folder. Delete is suggested. This is the finding the check exists for.
A cover for 4472, under a name this app never generated.	Probably a hand-made copy. Listed, deletion permitted, nothing pre-selected .
Cover-page-shaped, but not named by this app.	Very often somebody else's upload. Nothing pre-selected.

The check also reports the mirror problem as a note: **a style on the PO with no cover in the folder at all**. That is a delivery shortfall rather than a stray file, so it is not a row and has no button — repair it from the order's Delivery page.

Output files under the wrong name. An output is named once, at generation, and that name is then frozen. This check compares every other file against the name its layout resolves to **today**, so a layout edited after approval shows up as a rename rather than as a missing file.

THE VERDICT SAYS	WHAT IT MEANS, AND WHAT IS OFFERED
"Care label" for 4471 — the name the layout asks for today.	Fine. Second group.
"Care label" is under the name it was generated with, not the one its layout asks for now.	Rename in place is suggested. The artwork is approved and correct.
A stale copy of "Care label" — the correctly-named file is already here.	Delete is suggested. Nothing reads it any more.
"Hangtag" is delivering under its layout id — the layout has no file name.	The layout's file name is empty, so there is no correct name to rename to yet . Nothing is offered. Set a file name on the layout in the Output Builder first.
"Hangtag" leaked its layout id into the file name.	The layout has a proper name now. Rename in place is suggested.
Not one of ours — no document on this PO claims this name.	Left alone and counted as scanned. This check is about names <i>we</i> got wrong.

Cover pages are check one's subject and are deliberately skipped here, so no file is ever shown twice with two different remedies.

5 Deleting safely

This is the only screen in the app that removes a file from a supplier's folder, and a deletion there has no undo we control. So the safeguards are built into how it works, not into how carefully you click.

Confirm the changes to the supplier's folder

100423 – Acme Apparel – Northwind Knitwear / APPROVED LAYOUTS

Permanently delete 1 file

These leave the supplier's folder. The app cannot undo it — recovery means the SharePoint recycle bin.

00-4471-navy-cover-page.pdf

An old copy of 4471's cover — the current one is already in the folder.

Rename 1 file in place

Same file, same bytes, same version history — only the name changes.

4471-care-label.pdf → 4471-navy-care-label.pdf

Cancel

Delete 1 and rename 1

Deletes are listed first and separately from renames, and never folded together: one of the two is reversible and the other is not.

What the app guarantees when you press confirm

It re-reads the folder first. Nothing is acted on from the report you were shown. The check runs again against the live folder, and every file you ticked is validated against *that*.

Anything that changed is refused. A file renamed since the scan, or one the fresh check no longer flags, is left alone and reported back to you as refused — never acted on.

Only flagged rows, only the offered action. A file in the “looks right” group cannot be acted on at any price. A rename can only ever go to the one name the check resolved from the layout — you don’t get to type a name.

Files only, and only inside APPROVED LAYOUTS. The app has never written anywhere else. The PO folder above it holds the order’s own paperwork, which belongs to the customer and the supplier — those files are reported and never offered a button. Folders are never touched.

Nothing happens on its own. Nothing is on a schedule, and there is no “repair all”. A person picks the rows and confirms them by name, every time, and at most 100 files in one go. The fleet-wide sweep in section 6 finds work across every order but cannot do any of it — repairs only ever happen here, one folder at a time.

Every attempt is recorded — including the refusals and the failures, with the verdict you were shown, and who did it.

Afterwards, **What happened** lists the outcome file by file, and the report you are looking at is re-read so it can never show a picture that predates its own changes. Further down, **What this page has already changed on this PO** is the history for that order — there so that the person about to delete something can see what has already been removed, and by whom.

What this page has already changed on this PO

6 The same check, across every order

One folder at a time answers “is this order tidy?”. It never answers “how much of this is there, across the book?” — and that is the question worth planning around. **Check every PO**, the button at the top right of this page, runs the very same check on every purchase order in scope and collects what it finds in one place.

prod-spec.app / checks / sweep

Checks — every purchase order

Runs the folder check on every PO in scope and collects what it finds in one place, grouped by what is actually wrong.

Under the name it was generated with

142 files · 48 POs

The artwork is approved and correct; only the name is behind the layout’s current template.

Cover for a style that is not on this PO

4 files · 4 POs

It follows this app’s cover naming convention, so it was generated here and landed in the wrong folder.

Open a group and every file is listed with its purchase order, the same verdict that PO’s own check would show, and a link to open it there. **4**

- 1 **It takes about an hour, and it runs in the background.** One folder at a time, deliberately — going faster would only get the app throttled by SharePoint and slow every other page that reads a folder. Start it, close the tab, come back later.
- 2 **“Folders unreadable” is not the same as clean.** A folder that could not be listed is an absence of evidence, counted separately and listed further down with the reason. If a whole run of folders is unreadable the sweep stops rather than recording hundreds of rows that would read as “we looked and found nothing”.
- 3 **Grouped by the fault, not by the folder.** That is the point of the page. Per order, “one cover is under its old name” is a footnote; across the book, “142 files under an old name, all of them renameable” is a piece of work someone can plan — and the handful of judgement calls hiding among them become findable.
- 4 **Every row links back to that order’s own check.** That is where you act on it.

The sweep never touches a file

It renames nothing and deletes nothing. There is no button on it that could — not per file, not per group, not “fix all 142”. Its entire job is to tell you **which folders are worth opening**.

That is not caution for its own sake. A sweep’s findings are hours old by the time you read them, and colleagues rename things. Acting on a finding means opening that PO’s own check, where the folder is read *live* and every file is confirmed by name before anything happens — all the safeguards in section 5, unchanged. A bulk repair straight off a scan would be acting on a picture of the past.

It survives being interrupted

The list of orders is written before the work starts and each one is ticked off as its folder is checked, so nothing lives only in memory. If the app is deployed mid-run the sweep stops and the page says *Interrupted — resumable*: **Resume** picks up the orders it never reached and keeps everything it had already found. **Stop** ends a run early and keeps its findings too.

Scope: every purchase order at or above the supplier-send cutoff — the same orders whose documents actually leave the building. The number in force is shown on the page while a sweep runs.

7 When the folder can’t be read

No folder, no findings

If SharePoint refuses, throttles, or the order’s folder can’t be identified, the page tells you so and shows **no checks at all**. That is deliberate: a page saying “everything in this folder is unrecognised — delete?” during a brief outage would be actively dangerous. A failed lookup is never treated as evidence that a file is missing or wrong.

A good habit: run Checks on an order once its documents are approved and delivered. The flagged group tells you what to fix; the “files that look right” group tells you the check actually saw the folder. If a rename is offered, take it — it is the same file with the right name, and it never re-arms a supplier email. Once in a while, run **Check every PO** instead: it will not fix anything, but it tells you where the work actually is.
